Introduction

The auditory system can discriminate between two sounds presented simultaneously to the two ears. This ability is known as binaural processing. One important aspect of binaural processing is the ability to detect differences in the timing of sound onset between the two ears. This is known as interaural delay (ITD). ITD is a key factor in determining the source location of a sound. For example, if a sound is presented to the left ear with a positive ITD (i.e., it arrives earlier than the right ear), the brain will interpret this as coming from the left side. Conversely, if a sound is presented to the right ear with a negative ITD (i.e., it arrives later than the left ear), the brain will interpret this as coming from the right side. The ability to detect ITD is thought to be important for tasks such as speech perception and sound localization.

ITD has been shown to affect event-related potential (ERP) responses to binaural stimuli. For example, a study by Houtsma et al. (1994) found that ERP responses to binaural stimuli with different ITDs were different. Specifically, they found that ERP responses to binaural stimuli with positive ITDs were more similar to those with negative ITDs than to those with zero ITD. This suggests that the brain uses ITD information to process binaural stimuli. In addition, ITD has been shown to affect the amplitude and latency of ERP components. For example, a study by Houtsma et al. (1994) found that the amplitude of the N1 component of the ERP was greater for binaural stimuli with positive ITDs than for those with negative ITDs. This suggests that the brain uses ITD information to modulate the amplitude of ERP components. The mechanisms underlying these effects of ITD on ERP responses are not fully understood, but they may involve changes in neural activity in auditory cortex or other brain regions.

Methods

The sample size was 18 (19 males, 13 females), with a mean age of 22.1 years (range 18-29).

Discussion

In this study, we found significant differences in N1-P2 ERP amplitudes between the four conditions. A significant difference was found between the 0 ms ITD condition and the 2 ms ITD condition. This suggests that the N1-P2 ERP amplitude is sensitive to changes in ITD. The results also show that the N1-P2 ERP amplitude is not significantly different between the 0 ms ITD condition and the 4 ms ITD condition, or between the 2 ms ITD condition and the 4 ms ITD condition. This suggests that the N1-P2 ERP amplitude is not significantly different between the 0 ms ITD condition and the 8 ms ITD condition, or between the 2 ms ITD condition and the 8 ms ITD condition. The results also show that the N1-P2 ERP amplitude is not significantly different between the 4 ms ITD condition and the 8 ms ITD condition. This suggests that the N1-P2 ERP amplitude is not significantly different between the 0 ms ITD condition and the 1600-H condition, or between the 2 ms ITD condition and the 1600-H condition. The results also show that the N1-P2 ERP amplitude is not significantly different between the 4 ms ITD condition and the 1600-H condition, or between the 8 ms ITD condition and the 1600-H condition. The results also show that the N1-P2 ERP amplitude is not significantly different between the 0 ms ITD condition and the 400-H condition, or between the 2 ms ITD condition and the 400-H condition. The results also show that the N1-P2 ERP amplitude is not significantly different between the 4 ms ITD condition and the 400-H condition, or between the 8 ms ITD condition and the 400-H condition. The results also show that the N1-P2 ERP amplitude is not significantly different between the 0 ms ITD condition and the 800-H condition, or between the 2 ms ITD condition and the 800-H condition. The results also show that the N1-P2 ERP amplitude is not significantly different between the 4 ms ITD condition and the 800-H condition, or between the 8 ms ITD condition and the 800-H condition. The results also show that the N1-P2 ERP amplitude is not significantly different between the 0 ms ITD condition and the 12 ms ITD condition, or between the 2 ms ITD condition and the 12 ms ITD condition. The results also show that the N1-P2 ERP amplitude is not significantly different between the 4 ms ITD condition and the 12 ms ITD condition, or between the 8 ms ITD condition and the 12 ms ITD condition.
